

LARA-FILES

We are working on a file-system to database event-sourced system. The user will keep using his file system organization and our app will create a database and a nice UI for the user to find the documents. The user will not use any app for creating, renaming, deleting or moving folders or files. The app needs to watch changes in the file system to map them into the database.

We will use Laravel and the Spatie's package `laravel-event-sourcing` (v7) and Spatie's `file-system-watcher` package for real time watching. The `stored_events` table is now already being populated, using the code at the end of this explanation. So we have the initial events to work with. Now it's time to work on the first projector that will represent the file system.

We are using this system to manage the parts required to manufacture valves (.par) and the corresponding plans (.pdf), but the system should be product agnostic to keep it flexible. The main goal of the app is to help the user find the parts required to manufacture a valve and all the plans fastly, easily and with a great user experience.

We will have just one root or main folder-to-watch (let's call it /PLANOS). Inside it, we will have many directories. Each of these folders represents a main valve type (main product type) and the name of the main type corresponds to the folder name. All the folders (at different depths) inside the main valve type folder will represent different subtypes of the main product. A main type has no parent, but every subtype will have one parent.

There are three special folder names (once again we have to be flexible and be able to add more special folders): ARCHIVO, EN REVISION and all the folders that begin with 00 will have special treatment and should be ignored for the normal workflow.

Then we have the files. Each file represents a part of a product. The specific part to which each file belongs to, is defined by the file name excluding the extension and the revision (the path where the file lives is also important but the same file may live in different folders).

We will have three file extensions (but the system must be flexible and have the chance to add or remove file extensions to handle, for example .doc/x, xls/x or images like .jpg and .png will be added to the system soon but not yet): .par, .dft and .pdf. The .par files are SolidEdge 3D individual parts, .dft are SolidEdge 2D individual drawings and the .pdf are just the same drawings as the .dft but in a portable format.

Revisions are defined in the file-name. It's easy to extract the revision. All the revisions are in alphabetical and/or numerical order, so 'revA' is older than 'revB' and 'version24' is older than 'version25'.

We have to define what we call the file-name and the part-name. The file-name and the part-name are similar concepts. The part-name is the name of a physical part that will be used when assembling a product, obviously a part must be unique, but can exist different files with the same part-name in their file-names which will mean that they are linked to that part. In a file-name, the part-name is the substring of that file-name excluding the file extension and the revision. The part-name must be unique and it may have a .par, a .dft and a .pdf file or any other file extensions with the corresponding revisions. The files with different extensions that share the same part-name will be considered linked together to that part. This way a part may have linked to it a 3D model, a 2D drawing, an image, an excel file, a text file...

We will be able to set rules in a readable and flexible way in our app that will help the user eventually to keep the consistency of the file system and address hidden issues. The idea is that these rules will not stop the app, they will just warn the user about inconsistencies (remember that the user will keep manipulating the filesystem freely and this freedom is prone to inconsistencies).

Rules:

The same .par file may exist in different folders, but all of them must be the same (same content, same hash) and have the same file name. In fact, this is one of the core functionalities of the app: to be able to know in which products of our product range a specific part is used and also to warn if the same file-name with different content exists in the system (probably the oldest is outdated and can be a potential pitfall). The app also should warn if a file with the same content (hash) but different file-name has been found, as this situation should also be fixed by the user to keep the consistency of the system. We will need a column in the 'files' table called 'used_in' where we will store the path where each file is used.

On the contrary, only one .dft and .pdf may exist per '.par' file (one unique plan per part) in the whole main folder-to-watch. The app will work even if this rule is not accomplished, but it will keep track of these errors and eventually send notifications to the user until these kinds of discrepancies are resolved.

File-system example:

folder-to-watch/

- /MAIN-TYPE-1/ (#parent = null, depth=1)

- /SUB-TYPE-1 (#parent = MAIN-TYPE-1, depth=2)

- SUB-TYPE-1_PART-1.par (#parent = SUB-TYPE-1, depth = 3)

- SUB-TYPE-1_PART-1.dft

- SUB-TYPE-1_PART-1.pdf

- SUB-TYPE-1_PART-2.par

- SUB-TYPE-1_PART-2_revA.dft

- SUB-TYPE-1_PART-2_revA.pdf

- /SUB-TYPE-2 (#parent = SUB-TYPE-1, #depth = 3)

- SUB-TYPE-2_PART-1.par (#parent = SUB-TYPE-2, depth =4)

- SUB-TYPE-2_PART-1.dft

- SUB-TYPE-2_PART-1.pdf

- /SUB-TYPE-3 #parent = MAIN-TYPE-1

- SUB-TYPE-1_PART-1.par ()

- SUB-TYPE-3_PART-1.par

- SUB-TYPE-3_PART-2.dft

- SUB-TYPE-3_PART-2.pdf

- SUB-TYPE-3_PART-3.pdf

- SUB-TYPE-3_PART-3.dft

- SUB-TYPE-3_PART-4.dft

- MAIN-TYPE-1_PART-1.par
- MAIN-TYPE-1_PART-1.dft
- MAIN-TYPE-1_PART-1.pdf
- /MAIN-TYPE-2/
 - /MAIN-TYPE-2 SUB-TYPE-1
 - SUB-TYPE-1_PART-1.par
 - SUB-TYPE-1_PART-1.dft
 - SUB-TYPE-1_PART-1.pdf
 - SUB-TYPE-1_PART-2.par
 - SUB-TYPE-1_PART-2.dft
 - SUB-TYPE-1_PART-2.pdf
 - /SUB-TYPE-2
 - SUB-TYPE-1_PART-1.par
 - SUB-TYPE-1_PART-1.dft
 - SUB-TYPE-1_PART-1.pdf
 - SUB-TYPE-2_PART-1.par
 - SUB-TYPE-2_PART-2.dft
 - SUB-TYPE-2_PART-2.pdf
- MAIN-TYPE-1_PART-1.par
- MAIN-TYPE-1_PART-1.dft
- MAIN-TYPE-1_PART-1.pdf

STEP 1:

Write a projector that will populate the 'files' table, which will be a replica or a Model of the file-system (compendium of all the folders and files). At this step the rules don't matter, we just want to recreate the real state of the file-system in a database for fast search&find. This is the idea I have for the columns, but I am open to ideas. We will also need a migration for the 'files' table:

id	INTEGER	NO	NULL
path	varchar	NO	NULL
name	varchar	NO	NULL
file_type	varchar	NO	NULL
extension	varchar	YES	NULL
revision	varchar	YES	NULL
part_name	varchar	YES	NULL
product_main_type	varchar	YES	NULL
product_sub_type	varchar	YES	NULL
parent	varchar	YES	NULL
parent_path	varchar	YES	NULL
depth	INTEGER	NO	NULL
origin	varchar	NO	NULL
content_hash	varchar	YES	NULL
size	INTEGER	YES	NULL
modified_at	datetime	YES	NULL
created_at	datetime	YES	NULL
updated_at	datetime	YES	NULL

STEP 2:

Write the MasterFilesProjector.php. This projector will populate the 'masters' table for each event that will be used by the app to quickly find and provide the required .pdf documents to the user for all the .par files in a folder. Using a similar 'config' approach used in STEP 1 (FileSystemProjector), we will need a place where to define the file extensions that are candidates to become a 'master'. By the moment they will be: .par, .asm, .doc, .docx, .xls and .xlsx. To be a 'master' we need a 'slave', by the moment they will be: .pdf files but in the future other extensions may be candidates to be slaves. Following the approach in STEP1, we also require 'Directory name prefixes to omit' and 'Directory names that must be ignored completely' in the config file. The files in these directories will be omitted by this projector.

As the same .par file may live in multiple folders, we need a way to define one as the "master" of them. The 'master' will be a .par file (or .doc, .xlsx...). A specific .par file will be considered the master, if a slave .pdf with the same file name as the .par file (excluding the extension and revision) lives in the same folder as that .par file. The main goal of this app is to easily provide the unique slave .pdf document of any .par file used across the file system to the user. All the .par with the same name that live across the file system should have the same content as the 'master' (to be sure it's the same file copied across), but this rule will be monitored by another projector, it has nothing to do with this STEP 2. The same way, there should only exist one master, but this rule among others will be projected by another projector.

This projector must run only after the FileSystemProjector has run, as it will use the 'files' table as read-only to check whether the conditions for a file in the event stream to be a master are met. This projector also needs to remove from the table any file that after an event does not meet the conditions. We will need a migration and a model. The ideas for the columns could be:

path (the same as in 'files')

part_name (the same as in 'files')

master_revision (the same as in 'files')

extension (the same as in 'files')

parent_path (the same as in 'files')

content_hash (the same as in 'files')

slave_path (here will be the complete path to the .pdf file)

slave_revision (the same as in 'files')

modified_at (the same as in 'files')

(timestamps_columns)

STEP 3:

Write the PartsProjector.php. This projector will populate the 'parts' table for each event. This 'parts' table will be used by the app to quickly find and provide the required .pdf documents to the user for all the .par (docx, xlsx...) files in the whole file system. Using a similar 'config' approach used in STEP 1 and STEP 2 (FileSystemProjector and MasterFilesProjector), we will need a place to define the file extensions that are considered a 'part'. By the moment they will be: .par, .asm, .doc, .docx, .xls and .xlsx. A part may or may not have a corresponding 'master' in the 'masters' table. Following the approach in STEP1 AND 2, we also require 'Directory name prefixes to omit' and 'Directory names that must be ignored completely' in the config file. The files in these directories will be omitted by this projector.

For each file in the event-stream, using the 'files' and 'masters' tables as read-only, the PartsProjector will check if the file of the event can be considered a part and if it has a part with the same 'part_name' or the same 'content_hash' in the 'masters' table. If so, it will update the 'slave_path' column in the 'parts' table with the same 'slave_path' that exists in the 'masters' table, if not it will write 'NULL'. If the part's 'hash_content' is the same as in the 'masters' table, the 'content_as_master' column will be set to 'TRUE' and to 'FALSE' if not.

This projector must run only after the FileSystemProjector and the MasterFilesProjector have run, as it will use the 'files' and 'masters' tables as read-only to decide how to manage each file in the event stream. This projector also needs to update the 'parts' table after each new event. We will need a migration and a model. The ideas for the columns could be:

path (the same as in 'files')

part_name (the same as in 'files')

master_revision (the same as in 'files')

parent_path (the same as in 'files')

slave_path (as in 'masters' or 'NULL')

slave_revision (the same as in 'files')

content_hash (the same as in 'files')

content_as_master ('TRUE' or 'FALSE')

modified_at (the same as in 'files')

(timestamps_columns)

class InitialFileSystemScan extends Command

{

protected \$signature = 'filesystem:scan
{path : The path to scan}
{--no-progress : Disable progress bar}';

protected \$description = 'Perform initial scan of file system and create events';

// Constructor to set custom help message

public function __construct()

{

parent::__construct();

\$this->setHelp(<<<'HELP'

DESCRIPTION:

Perform the initial scan of a directory and record filesystem events in the database.

This command will:

- Recursively scan the `given` directory
 - Generate events `for` every file `and` directory found
 - Store these events in the ``stored_events`` table
 - Display statistics `and` sample events at completion
- 💡 Use `for` initial setup - `not` recommended `for` active systems.

USAGE:

```
php artisan filesystem:scan <path> [options]
```

ARGUMENTS:

| | |
|-------------------|----------------------------------|
| <code>path</code> | Absolute path to scan (required) |
|-------------------|----------------------------------|

OPTIONS:

| | |
|----------------------------|--|
| <code>--no-progress</code> | Disable progress bar display (useful <code>for</code> CI environments) |
|----------------------------|--|

OUTPUT:

- Progress bar showing current file being processed (`unless` disabled)
- Summary table with metrics:
 - Directories found
 - Files found
 - Total size
 - Errors encountered
 - Events created
 - Duration
 - Items per second
- Sample of `last 5` events created

SCANNING BEHAVIOR:

- Processes both files `and` directories
- Follows symbolic links
- Skips unreadable paths (counted as errors)
- Records creation events `for` all found items

SAMPLE OUTPUT:

Starting initial file `system` scan...

Path: `/var/www`

✅ Initial scan completed successfully!

| Metric | Value |
|-------------------|-------------|
| Directories found | 1,024 |
| Files found | 12,345 |
| Total size | 1.23 GB |
| Errors | 3 |
| Events created | 13,369 |
| Duration | 5.2 seconds |
| Items per second | 2,571 |

📋 Sample events created (last 5):

| Event | Path | Type | Created |
|-------------|-----------|-----------|---------------------|
| FileCreated | image.jpg | file | 2023-01-01 12:34:56 |
| DirCreated | documents | directory | 2023-01-01 12:34:55 |

EXAMPLES:

1. Scan with progress bar:
`php artisan filesystem:scan /home/user/documents`
2. Scan without progress bar:
`php artisan filesystem:scan /mnt/data --no-progress`

NOTES:

- Requires `write` permission to the database
- Large directories may take significant `time`
- Check error count `for` accessibility issues

```

```

```
    public function __construct()
    {
```

```
parent::__construct();
```

```
$this->setHelp(<<<'HELP'
```

DESCRIPTION:

Monitor the stored_events table to verify real-time persistence of filesystem events.
Displays new events as they occur in the database with color-coded event types.

Features:

- Shows historical events before starting live monitoring
- Color-coded event types for quick identification:
 - Green: File/Directory creation
 - Blue: File modification
 - Red: File/Directory deletion
- Normalizes Windows paths to Unix-style
- Graceful exit with Ctrl+C

USAGE:

```
php artisan events:monitor-db [options]
```

OPTIONS:

```
--delay=<seconds>    Delay between processing events (minimum 0.5s) [default: 1s]  
--last=<number>       Show last N historical events before monitoring [default: 5]
```

EXAMPLES:

Start monitoring with default settings:

```
php artisan events:monitor-db
```

Monitor with custom settings (show last 3 events, 0.5s delay):

```
php artisan events:monitor-db --last=3 --delay=0.5
```

OUTPUT FORMAT:

```
[LIVE] [HH:MM:SS] <ICON> <COLORED_EVENT_TYPE>: <PATH>
```

```
[HIST] [HH:MM:SS] <ICON> <COLORED_EVENT_TYPE>: <PATH>
```

Prefixes:

```
[LIVE] - Real-time events detected during monitoring
```

[HIST] - Historical events shown at startup

Icons:

-  - File event
-  - Directory created
-  - Directory deleted
-  - File modified
-  - File deleted
-  - Unknown event type

COLOR SCHEME:

- \e[32mGreen\e[0m - File/Directory creation
- \e[34mBlue\e[0m - File modification
- \e[31mRed\e[0m - File/Directory deletion

```

class ReconcileFileSystem extends Command

```

```

{
    protected $signature = 'filesystem:reconcile
                            {path : The path to reconcile}
                            {--skip-scan : Skip filesystem scan, use last state}';

    protected $description = 'Reconcile file system state with event history';

    // Constructor to set custom help message
    public function __construct()
    {
        parent::__construct();

        $this->setHelp(<<<'HELP'

```

DESCRIPTION:

Reconcile the current file **system state** with stored event history.

This command will:

1. Scan the target directory (**unless** skipped)
2. Compare current **state** against stored events
3. Identify discrepancies (missing/modified files)
4. Generate reconciliation events to fix inconsistencies
5. Output summary statistics

💡 Recommended **for** periodic maintenance **and** data integrity checks.

WORKFLOW:

```

[Scan Phase]      : Scan file system (optional, unless --skip-scan used)
[Comparison Phase]: Compare against last known state from events
[Reconciliation]  : Generate events to fix discrepancies
[Reporting]       : Show results table

```

USAGE:

```

php artisan filesystem:reconcile <path> [options]

```

ARGUMENTS:

path Absolute path to reconcile (required)

OPTIONS:

--skip-scan Use **last** scan **state** instead of re-scanning (faster)

OUTPUT:

- Summary table with reconciliation metrics:

- Items scanned
- Discrepancies found
- Events created
- Duration
- Items per second

EXAMPLES:

1. Full reconciliation with new scan:

php artisan filesystem:reconcile /var/www

2. Fast reconciliation using **last** scan **state**:

php artisan filesystem:reconcile /mnt/data --skip-scan

SAMPLE OUTPUT:

Starting file **system** reconciliation...

Path: **/var/www**

✓ Reconciliation completed successfully!

| Metric | Value | |
|-------------------------------|---------|--|
| Items scanned | 15,342 | |
| Discrepancies found | 27 | |
| Reconciliation events created | 27 | |
| Duration | 8.3 sec | |
| Items per second | 1,848 | |

NOTES:

- Without --skip-scan: Does fresh scan (slower but more accurate)
- With --skip-scan: Uses **last** scan **state** (faster but requires recent scan)
- Discrepancies include: missing files, modified files, orphan events
- Created events will fix inconsistencies in the event history
- Run during low-traffic periods **for** large directories

* Return the revision (e.g. "revA", "v1", "20250617") or NULL when the tail

* does not match one of the allowed patterns[1].

*

* — How the unified regular expression works —————

* 1. rev[0-9a-z]+ → matches strings that start with “rev” followed by

* one or more digits or lowercase letters, e.g. “revA”, “rev01”[1].

* 2. v[0-9]+[a-z]* → matches strings that start with “v” (upper- or

* lower-case) followed by one or more digits and *optionally* a

* trailing letter sequence, e.g. “v1”, “V1”, “v2b”, “v10a”[2].

* 3. [0-9]{8} → matches exactly eight consecutive digits, which we

* use for dates like “20250617” (YYYYMMDD)[3].

* 4. The /i modifier makes the whole pattern case-insensitive, so

* “_V1” and “_v1” are treated the same[4].
